

## PET328: COMPUTER APPLICATIONS IN PETROLEUM ENGINEERING (With Python Programming)

## Olatunde O. Mosobalaje (PhD)

Department of Petroleum Engineering, Covenant University, Ota Nigeria

#### OUTLINE

- Preambles
  - The Appetizer
  - The Toolbox
  - The Embedded Course
  - Introduction to Computer Programming
    - Getting Started with Python
      - Basic Python Objects
      - Conditional Execution
      - Repeated Execution
      - Functions
- Python Data Structures
  - Strings
  - Lists
  - Tuples
  - Dictionaries Some Python Libraries
    - NumPy
    - Matplotlib
    - Pandas
    - Scikit-learn

- Oil Reservoir Volumetrics
- Material Balance Analysis
- PVT Properties

# The Appetizer – a presentation

ACQUIRING NASCENT SKILLS FOR EMERGING OIL AND GAS
OPPORTUNITIES: DATA ANALYTICS, MACHINE LEARNING AND
ARTIFICIAL INTELLIGENCE

#### The Toolbox

- For this course, the following tools would be needed:
  - Python 3
  - Python Integrated Development and Learning Environment (IDLE)
  - Git and GitHub

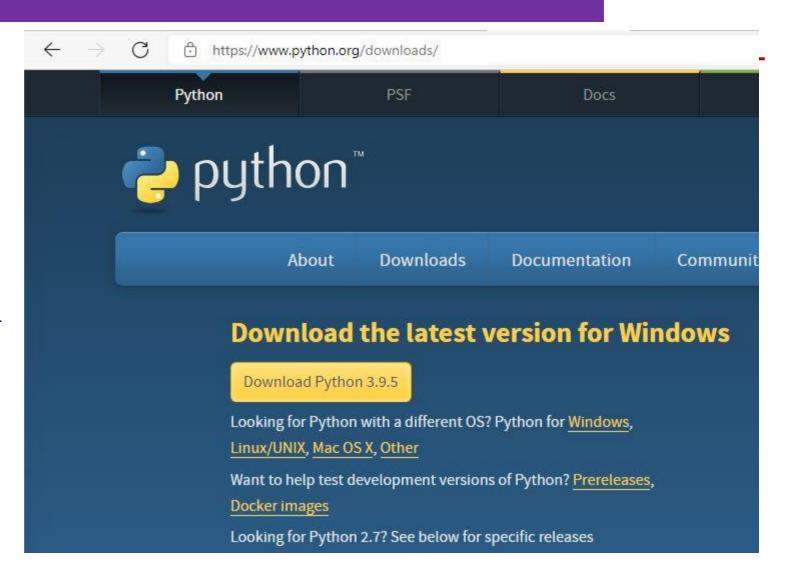

#### The Toolbox

Installing Python 3

To install the latest release of Python

3, go to Python download website:

https://www.python.org/downloads/

#### The Toolbox

Installing Python 3

Launch the downloaded executable file by doubleclicking the file in your download folder.

Follow the steps as the installer leads

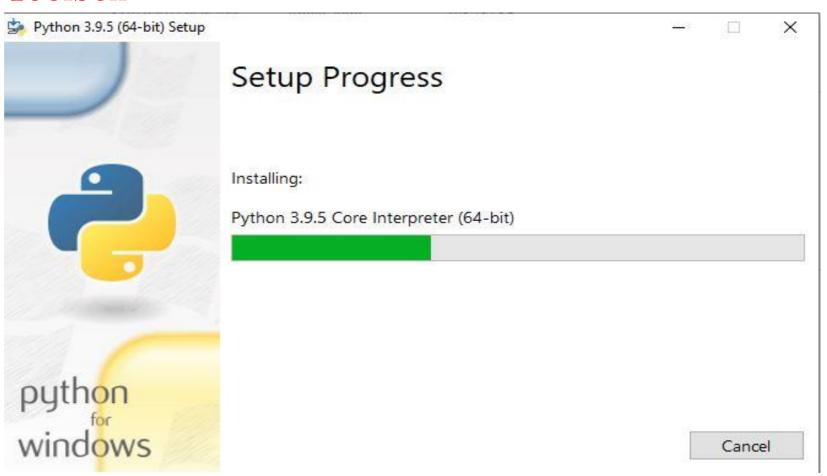

Click on the default installation option.

Ensure to check the Add Python 3.9 to PATH

#### The Toolbox

Installing Python 3

#### The Toolbox

Installing Python 3

Click the close button when the installation is completed

#### Setup was successful

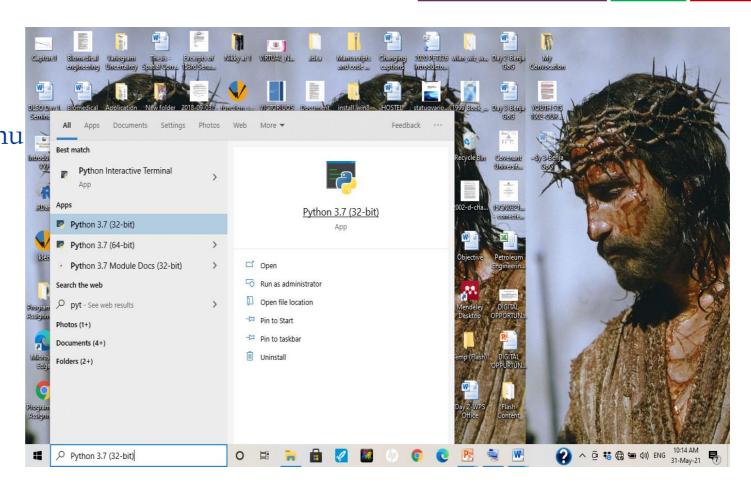

New to Python? Start with the online tutorial and documentation. At your terminal, type "py" to launch Python, or search for Python in your Start menu.

See what's new in this release, or find more info about using Python on Windows.

Close

Launching Python 3

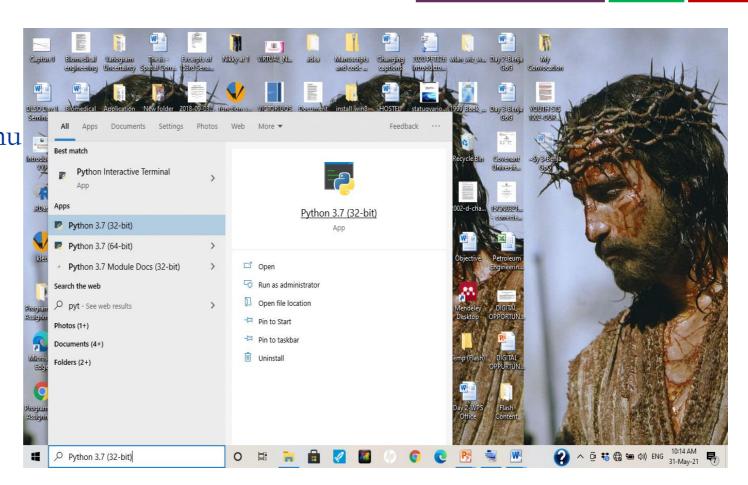

Simply type Python into the Start Menu search box and click the Python program.

#### The Toolbox

Launching Python 3

Simply type Python into the Start Menu search box and click the Python program.

#### The Toolbox

Launching Python 3

```
Python 3.9 (64-bit)
Python 3.9.5 (tags/v3.9.5:0a7dcbd, May 3 2021, 17:27:52) [MSC v.1928 64 bit (AMD64)] on win32 Type "help", "copyright", "credits" or "license" for more information.
```

#### The Toolbox

### Python IDLE

Now, the Python DOS-like environment seems

boring. Good enough, we will typically not be

working on that platform; rather we will interact

with Python from a platform known as

Interactive Development and Learning

Environment (IDLE)

#### The Toolbox

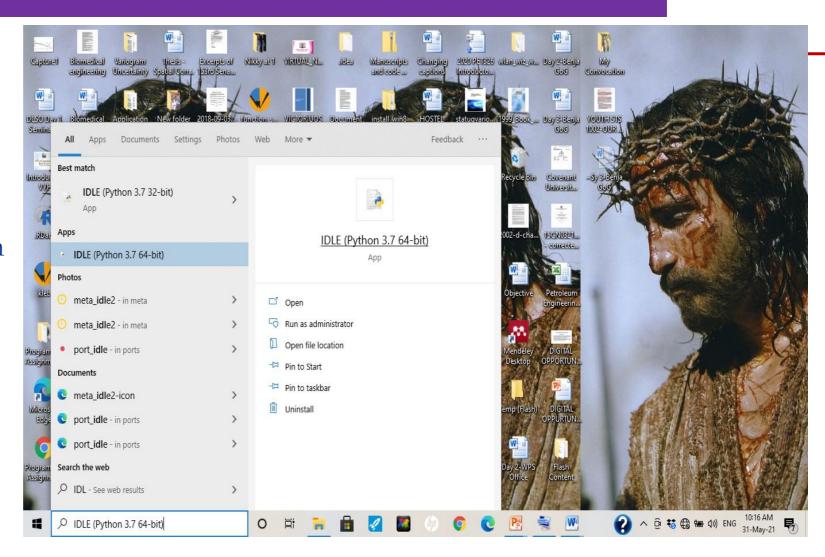

Python IDLE

To launch IDLE, simply type

IDLE into the Start Menu search

box and click on the IDLE

program.

#### The Toolbox

Python IDLE

```
IDLE Shell 3.9.5
                                                                                 ×
File Edit Shell Debug Options Window Help
Python 3.9.5 (tags/v3.9.5:0a7dcbd, May 3 2021, 17:27:52) [MSC v.1928 64 bit (AM
D64)] on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>>
```

#### The Toolbox

Python IDLE

There are two ways by which you could

communicate with Python from the IDLE

environment:

- Interactive
- From a file (script)

Communicating with Python interactively
In this case, you type in Python command
(one at a time) into the console. Each
command get executed once the 'Enter' key is

pressed. Depending on the command, results

may be displayed on the console once the command is executed.

```
IDLE Shell 3.9.5
File Edit Shell Debug Options Window Help
Python 3.9.5 (tags/v3.9.5:0a7dcbd, May 3 2021, 17:27:52) [MSC v.1928 64 bit (AM
D64) | on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>> poro = 0.34
>>> print (poro)
0.34
>>> Area = 40
>>> print (Area)
>>> PayThickness = 15
>>> print(PayThickness)
15
>>> BV = Area*PayThickness
>>> print(BV)
>>> PV = BV*poro
>>> print (poro)
0.34
>>> print(PV)
>>> print('The bulk volume of the reservoir is', BV)
    bulk volume of the reservoir is 600
>>> print('The bulk volume of the reservoir is', BV, 'Acre-ft')
The bulk volume of the reservoir is 600 Acre-ft
>>>
```

Communicating with Python interactively
In this case, you type in Python command
(one at a time) into the console. Each
command get executed once the 'Enter' key is
pressed. Depending on the command, results
may be displayed on the console once the

```
IDLE Shell 3.9.5
File Edit Shell Debug Options Window Help
Python 3.9.5 (tags/v3.9.5:0a7dcbd, May 3 2021, 17:27:52) [MSC v.1928 64 bit (AM

>>> print (Area)
>>> PayThickness = 15
>>> print (PayThickness)
15
>>> BV = Area*PayThickness
>>> print(BV)
>>> PV = BV*poro
>>> print (poro)
0.34
>>> print(PV)
>>> print('The bulk volume of the reservoir is', BV)
    bulk volume of the reservoir is 600
>>> print('The bulk volume of the reservoir is', BV, 'Acre-ft')
The bulk volume of the reservoir is 600 Acre-ft
>>>
```

command is executed.

#### The Toolbox

Communicating with Python from a file In this case, you type in Python commands (all at a time) into a text file editor (code editor). The commands don't get executed as

executed (sequentially) when submitted as a whole to the Python interpreter.

they are being typed. Rather, they get

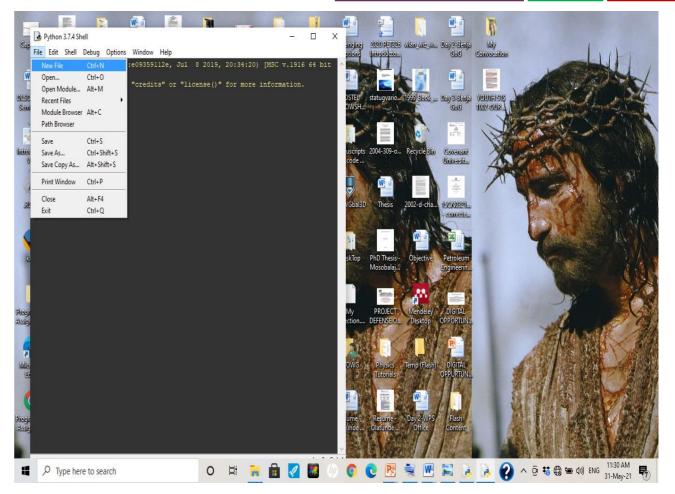

#### The Toolbox

Communicating with Python from a file

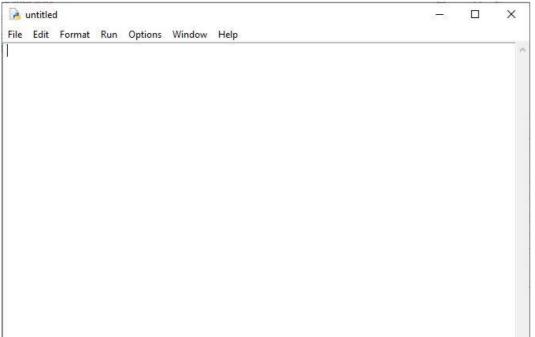

Any text editor program could be used for this purpose, as long as the file is saved as a .py file.

Good, Python has an in-built text editor for this purpose.

Communicating with Python from a file To launch Python's in-built code editor, just click on the File menu and choose New File.

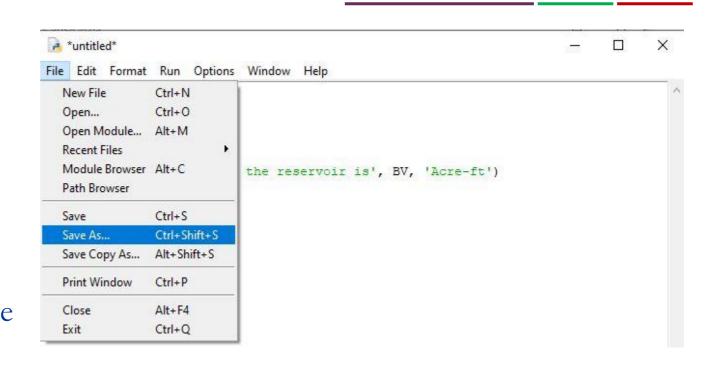

Communicating with Python from a file

Once the editor is opened, you can type in your lines of codes.

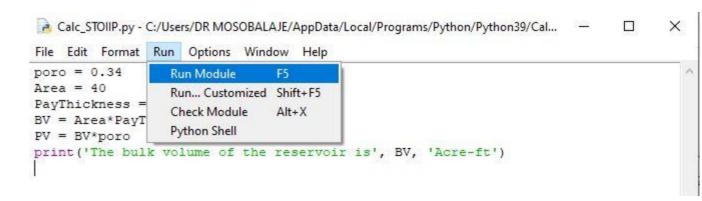

Communicating with Python from a file Before submitting the lines of codes in the code editor to the Python interpreter, you need to save the editor file.

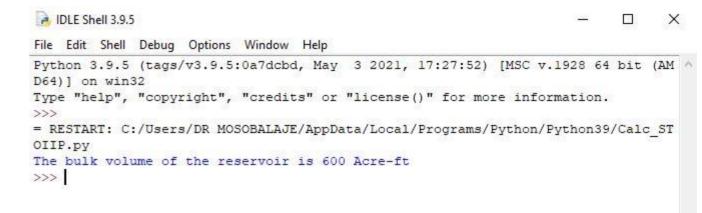

To save, simply go the File menu and choose

Communicating with Python from a file
Once the file (script) is saved, the code lines
can be submitted to the Python interpreter by
choosing item 'Run Module' in the Run

The output of the code execution (if any) is subsequently displayed on the Python console.

menu.

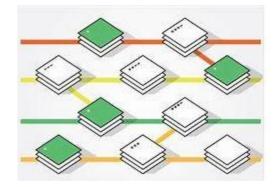

#### The Toolbox

Git is an open source version control software.

#### What is Version Control?

Version control (VC) is a system used for keeping track of changes made to a file over time. As the changes are made, the system records and save the state of the file at instances indicated by the user. Such user can revert back to a previous version of the file when necessary.

Essentially, the VC system keeps the latest version of the file but also keeps a record of all changes between all versions.

#### The Toolbox

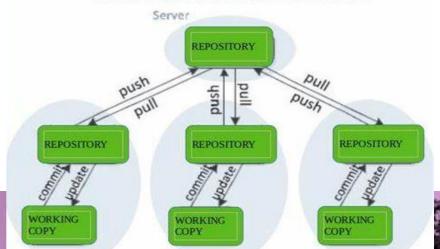

Git and GitHub

And, there is something called Distributed Version Control (DVC)

#### What is Distributed Version Control?

Typically, real life projects (including oilfield digital projects) are done by teams whose members need to collaborate – work together on same files. Individual members of the team can make changes to such shared files. There is therefore a need to make such file available on a central server and to keep track of the following: Distributed version control

- who made what change?
- When was the change made?
- Why was the change made?

#### The Toolbox

And, there is something called Distributed Version Control (DVC)

#### What is Distributed Version Control?

A version control system that also comes with the capabilities for collaboration among several people is known as Distributed Version Control system.

Git is a version control system – locally hosted on your system.

GitHub is an online platform that interfaces with Git, hosting your files on remote servers thereby making them available for collaboration with others.

#### The Toolbox

Git and GitHub

In this course, we shall be working as a team, therefore, both Git and GitHub are part of tools we shall be using. Essentially, submissions to some assignments shall be in the form of code file editing and sharing between students and the Course Instructor.

# Assignment 1

Get the following tools ready on your PC:

- dit install
- A user account on github.com
- GitHub desktop install

#### The Embedded Course

A Coursera course is embedded into this course (PET328). It is compulsory that all students completes the Coursera course as it is part of the assessment items in PET328.

#### The Embedded Course

The embedded course is titled 'Programming for Everybody (Getting Started with Python).

The course is offered by University of Michigan.

Programming for Everybody (Getting Started with Python)

#### The Embedded Course

The link to the embedded course has been added to the PET328 course site on Moodle. To enroll for the Coursera course, simply click on the link.

Programming for Everybody (Getting Started with Python)

When you complete the course, you are awarded a certificate of completetion!!!

## Introduction to Computer Programming

- Analogy: Programming language vs. Natural language
  - There is a striking similarity between learning programming language and learning natural language. In both cases, the process is thus:
    - learn the vocabulary and the grammar spell words, construct sentences etc.
    - Communicate
      - natural language: use words, sentences, paragraphs to communicate an idea
      - Programming language: use keywords, variables, functions, expressions, statements to communicate steps to computer.

## Introduction to Computer

## Programming

A program is simply a collection of sequential Python statements written to perform a specific task

```
i in people.data.users:
response = client.api.statuses.user_timeline.get(screen
      'Got', len(response.data), 'tweets from', i.screen
  len(response.data) != 0:
    ltdate = response.data[0]['created_at']
    ltdate2 = datetime.strptime(ltdate, %a %b %d %H:%M:%
   today = datetime.now()
    howlong = (today-ltdate2).days
    howlong daywindow:
             i.screen_name, 'has tweeted in the past'
       totaltweets - len(response.data)
        for j in response.data:
            if j.entities.urls:
                for k in j.entities.urls:
                   newurl = k['expanded_url']
                   urlset.add((newurl, j.user.screen_name
            i.screen_name, 'has not tweeted in the pas
```

# Introduction to Computer Programming

### Fundamental patterns (concepts) in a program

- The following are typical patterns (statement(s)) you see in a program:
  - Input statements
  - Output statements
  - Sequential execution
  - Conditional statements
  - Repeated execution (loops)
  - Reuse of statements (functions)

# Introduction to Computer

Programming

Fundamental patterns (concepts) in a program

- Input statements: used to request and accept data from users
- Example: the input function.

```
Input_Output_demo.py - C:\Users\TTOWG\645\1 karia def\2. CU\CU Courses\PET328 - Computer Applications in Petroleum
File Edit Format Run Options Window Help
#...TTOWG!
# input statements
poro = input('Enter the value of porosity: ')
area = input('Enter the value of area: ')
paythickness = input('Enter the value of pay zone thickness: ')
area = float(area)
paythickness = float(paythickness)
BV = area*paythickness
# output statement
print('The bulk volume of the reservoir is', BV, 'Acre-ft')
```

This script is available <u>here</u>

https://github.com/TTOWG/PET328 2021 Class/blob/main/demo\_l

# Introduction to Computer

# Programming

Fundamental patterns (concepts) in a program

- Output statements: used to display the results of execution on the screen.
- Example: the print function

```
Input_Output_demo.py - C:\Users\TTOWG\645\1 karia def\2. CU\CU Courses\PET328 - Computer Applications in Petroleum
File Edit Format Run Options Window Help
#...TTOWG!
# input statements
poro = input('Enter the value of porosity: ')
area = input('Enter the value of area: ')
paythickness = input('Enter the value of pay zone thickness: ')
area = float(area)
paythickness = float(paythickness)
BV = area*paythickness
# output statement
print('The bulk volume of the reservoir is', BV, 'Acre-ft')
```

### Introduction to Computer

# Programming

Fundamental patterns (concepts) in a

#### program

- Sequential execution: typically, a program would entail multiple statements.
- Statements are executed in the order (sequence) in which they are encountered.
- Latter statements can make use of results of former statements; not vice-

```
Input_Output_demo.py - C:\Users\TTOWG\645\1 karia def\2. CU\CU Courses\PET328 - Computer Applications in Petroleum
File Edit Format Run Options Window Help
#...TTOWG!
# input statements
poro = input('Enter the value of porosity: ')
area = input('Enter the value of area: ')
paythickness = input('Enter the value of pay zone thickness: ')
area = float(area)
paythickness = float(paythickness)
BV = area*paythickness
# output statement
print('The bulk volume of the reservoir is', BV, 'Acre-ft')
```

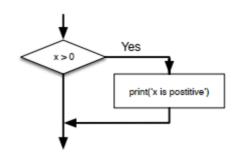

### Introduction to Computer

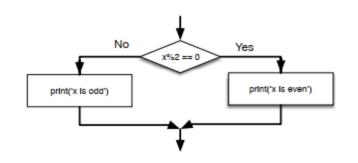

# Programming

Fundamental patterns (concepts) in a

#### program

- Conditional Statements: patterns that make it possible for the program to check for some conditions and decide to:
  - perform a statement(s) or skip the statement(s)
  - Choose between alternative statements.

```
a conditional_statement_demo.py - C:\Users\TTOWG\645\1 karia def\2. CU\CU Courses\PET328 - Computer Applications in Petroleum Enginee
File Edit Format Run Options Window Help
#...TTOWG!
initial pressure = input('Enter the value of initial pressure: ')
bubble pressure = input('Enter the value of bubble-point pressure: ')
initial pressure = float(initial pressure)
bubble_pressure = float(bubble_pressure)
 finitial pressure > bubble pressure:
   print('The reservoir is undersaturated!!!')
   print('The reservoir is saturated!!!')
```

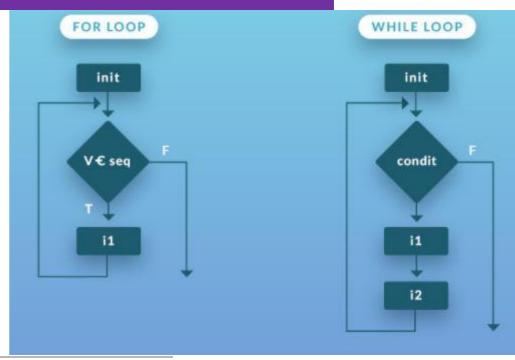

## Introduction to Computer

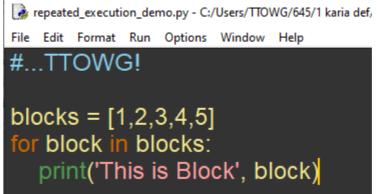

# Programming

Fundamental patterns (concepts) in a

#### program

Repeated Execution: patterns that instructs the program to perform (iterate) a given statement(s) repeatedly, for each item in a set of items, varying values of parameter(s) from item to item.

### Introduction to Computer

# Programming

Fundamental patterns (concepts) in a

#### program

- Re-use of statements: the task performed by some statement(s) might be routine and needed at various points in your program.
- Such statement(s) may be written once, saved with a name and re-used at various points in your program by referring to the name.

```
statement_reuse_demo.py - C:\Users\TTOWG\645\1 karia def\2. CU\CU Courses\PET328 - Computer Applications in Petroleum Engineering\Demos\statement_reuse_de
    Edit Format Run Options Window Help
#...TTOWG!
# function definition
    f stoiip  calc(area, thickness, poro, sw, boi):
   STOIIP = (7758*area*thickness*poro*(1-sw))/boi
   return STOIIP
# function call for Reservoir TTOWG 1 (re-use)
oil_inplace_TTOWG_1 = stoiip_calc(40, 15, 0.3, 0.28, 1.2)
print('The amount of oil in place in Reservoir TTOWG_1 is', oil_inplace_TTOWG_1, 'STB')
# function call for Reservoir TTOWG 2 (re-use)
oil_inplace_TTOWG_2 = stoiip_calc(80, 10, 0.23, 0.35, 1.1)
print('The amount of oil in place in Reservoir TTOWG_2 is', oil_inplace_TTOWG_2, 'STB')
```

>>>print('...to the only wise God')
```

Coming Soon...

Season 1 Episode 2 –

Getting Started with Python

### Basic Python Objects

Crudely speaking, Python objects are stuffs upon which actions (specified in python commands) are performed.

Example: in the code screenshot shown, 3, 4, j, k, 7, mantra, 'TTOWG' are all objects acted upon.

```
Python 3.7.4 Shell
File Edit Shell Debug Options Window Help
Python 3.7.4 (tags/v3.7.4:e0935
Type "help", "copyright", "credit
>>> 3*4
>>> j = 12
>>> k = j+7
>>> mantra = 'TTOWG!'
>>> print(mantra)
TTOWG!
>>>
```

### Basic Python Objects

- The basic Python objects considered here are Values and Variables.
- Later, some sets of sophisticated objects known as data structure shall be considered.

### Basic Python Objects

#### Values

Values are simply the representation of data entities.

### Types of Values

- Values in Python belong to various types such as type *integer*, type *float*, and type *string*.
- Use the function *type* to find out the type to which a value belong.

```
<class 'int'>
>>> type('TTOWG!')
<class 'str'>
>>> type(2.0)
<class 'float'>
>>> type('2')
<class 'str'>
```

### Basic Python Objects

### Types of Values

- 2 is of type (class) integer
- TTOWG' and '2' are of type string; just like any set of characters (alphanumeric and nonalphanumeric) enclosed in quotes
- ₱ 2.0 is of type float; just as are all numbers expressed in decimals.

```
<class 'int'>
>>> type('TTOWG!')
<class 'str'>
>>> type(2.0)
<class 'float'>
>>> type('2')
<class 'str'>
```

## Basic Python Objects

### Types of Values

- Please, take note that users' response to the input function prompt is stored as a string.
- Before using such *input* in a mathematical operation, they should be converted to a numerical type using *float* or *int* functions.

```
Pvthon 3.7.4 Shell
File Edit Shell Debug Options Window Help
Python 3.7.4 (tags/v3.7.4:e09359112e, Jul 8 2019, 19:29:22)
Type "help", "copyright", "credits" or "license()" for more infor
>>> poro = input('What is the value of porosity?')
What is the value of porosity?0.34
>>> print(poro)
0.34
>>> type(poro)
<class 'str'>
>>> poro/0.01
Traceback (most recent call last):
 File "<pyshell#3>", line 1, in <module>
  poro/0.01
TypeError: unsupported operand type(s) for /: 'str' and 'float'
>>> # The division operation failed because
>>> # the value 0.34 is a string; not a number.
>>> poro = float(poro)
>>> type(poro)
<class 'float'>
>>> poro/0.01
34.0
```

### Basic Python Objects

#### Variables

- A variable is a value stored in memory and referred to with a chosen name.
- In other words, values are assigned to variables.
- When the name of a variable is called, the value assigned therein answers.

# Basic Python Objects

#### Variables

- A raw value can be assigned to a variable.
  - Example: j is a variable; the value 12 is assigned to it.
- Also, the output of an expression (involving a variable) may be stored in another variable.
  - Example: k is a variable, the value obtained when j+7 is executed is subsequently assigned to variable k.
- Not only numeric values are assigned to variables, strings are also assigned.
  - Example, mantra is a variable with string 'TTOWG!' assigned to it.

```
Python 3.7.4 Shell
File Edit Shell Debug Options Window Help
Python 3.7.4 (tags/v3.7.4:e0935
Type "help", "copyright", "credit
>>> 3*4
12
>>> j = 12
>>> k = j+7
>>> mantra = 'TTOWG!'
>>> print(mantra)
TTOWG!
```

### Basic Python Objects

### Choosing Variable Names

- In naming variable, the following rules are recommended:
  - Variable names should be descriptive, as much as possible. That is, the name should somewhat tell us something about the variable. Example: a variable to hold the value of reservoir permeability is better named 'perm' than named 'x'
  - The name must be a single word. Where multiple words are necessary for descriptive purposes, they can be joined with the underscore character; e. g.: init\_pressure.
  - Names should not be too long.
  - Names may contain both alphabets and numbers; but must not start with numbers.
  - Names are case sensitive. If you named a variable as 'poro', do not refer to it as 'Poro'.
  - Avoid using special characters like '@', '\$' in names.

## Basic Python Objects

### Keywords

- Reywords are words that are reserved for Python's in-built structure.
- Here is the list of Python's keywords.
- Keywords cannot be used as variable names; doing so would cause error.

and	del	from	None	True
as	elif	global	nonlocal	try
assert	else	if	not	while
break	except	import	or	with
class	False	in	pass	yield
continue	finally	is	raise	async
def	for	lambda	return	await

## Basic Python Objects

#### Statements

- A statement is simply unit of code (commands) that is interpretable and executable by Python; just like a sentence in natural language.
- Two common types of Python statements are Assignment statements and Expressions.
- Assignment statements simply assigns values to a variable.
- An expression is a statement that combines variables, values, functions and operators.
- A statement could combine both types such that the result of an expression (RHS) is assigned to a variable (LHS).

```
poro = 0.27 # This is an assignment statement.
```

area = 40 # This is an assignment statement.

thickness = 15 # This is an assignment statement.

area\*thickness # This is an expression.

# Basic Python Objects

#### Multi-line statements

- Typically, a Python statement is written in a single line.
- However, if the statement is too long, it could be continued in the next line; but the current line should end with the line continuation character i.e.

### Multiple statements in a line

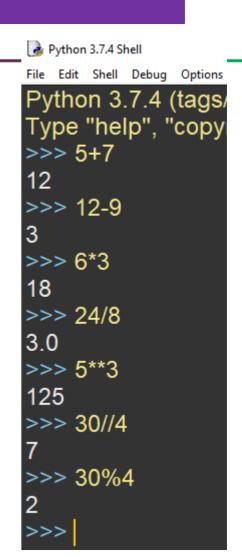

Writing multiple statements in same line is not encouraged; however, if that has to be done, the statements should be separated by semicolon.

```
>>> poro = 0.18; area = 40; thickness = 15
>>> print(area)
40
>>>
```

## Basic Python Objects

### Operators

- Operators are symbols of mathematical operations.
  - + for addition
  - for subtraction
  - \* for multiplication
  - / for division
  - \*\* for exponentiation (raise to power)
  - // integer division (truncates the result of division to its integer part.
  - % modulus (gives the remainder of an integer division).
- The objects acted upon by operators are called operands.

### Basic Python Objects

### Order of Operations

- When multiple operations are featured in a statement, Python executes them in the order specified by the accronym: PE-MD-AS (Parenthesis, Exponentiation, Multiplication, Division, and Subtraction).
- You can used parenthesis to dictate the order you desire.
- Multiplication and Division has equal precedence; hence are executed left to right.
- Addittion and Subtraction has equal precedence; hence are executed left to right.
- You may also use parenthesis to make an expression more readable and less confusing.
- Nested parenthesis are executed from inside to outside.

### Basic Python Objects

### Order of Operations

Consider the following operations to convince yourself of the PEMDAS order.

```
Python 3.7.4 Shell
File Edit Shell Debug Options Window Help
Python 3.7.4 (tags/v3.7.4:e09359112e, Jul 8 2019, 19:29:22) [MSC v.19
Type "help", "copyright", "credits" or "license()" for more information.
>>> (3+5)**(9-6)
512
>>> 14+(3+5)**(9-6)
526
>>> # No, I mean the result of 14+(3+5) should be raised to power 9-6
>>> # Oh! Use parenthesis to dictate that order:
>>> (14+(3+5))**(9-6)
10648
>>> 14+(3+5)**(9-6)/10
65.2
>>> (14+(3+5)**(9-6))/10
52.6
>>> (14+(3+5))**(9-6)/10
1064.8
```

### Basic Python Objects

### String Operations

- Strings can be joined end-to-end by using the + operator. If you want a space between the strings, then include it in one of the strings.
- Also, a string can be repeated multiple times using the \* operator (with and integer, of course).

```
File Edit Shell Debug Options Window Help
Python 3.7.4 (tags/v3.7.4:e09359112e, Jul 8 2019, 19
Type "help", "copyright", "credits" or "license()" for mo
>>> 'TTOWG!' + 'to the only wise God'
'TTOWG!to the only wise God'
>>> # Oh, I need space
>>> 'TTOWG! ' + 'to the only wise God'
'TTOWG! to the only wise God'
>>>
>>> 'TTOWG!'*3
'TTOWG!TTOWG!TTOWG!'
>>> 'TTOWG! '*3
'TTOWG! TTOWG! TTOWG! '
>>> 3*'TTOWG! '
'TTOWG! TTOWG! TTOWG! '
>>>
```

#### Conditional Statements

- Conditional statements are written to make it possible for a program to check for some conditions and decide to:
  - perform a statement(s) or skip the statement(s)
  - Choose between alternative statements.
- So, the concept of condition is central to this kind of statements.
- These conditions are crafted using the concept of Boolean expressions.

#### Conditional Statements

### Boolean Expressions

- A boolean is a value that is either True or False
- Just like the integer type can take values 1, 2, 3 e.t.c; the boolean type can take one of just two values: True or False.
- For this reason, 'True' and 'False' are Python keywords reserved for boolean values; a variable must not be named using these words.
- Now, a boolean expression is essentially a comparison expression that evaluates to either True or False.

```
<class 'bool'>
>>> type(False)
<class 'bool'>
>>>
>>> 2<7
True
>>> 2>7
False
>>>
```

#### Conditional Statements

# Boolean Expressions

- Boolean expressions are constructed using comparison operators listed here.
- ♣ Take note that = is an assignment operator while == is a comparison operator.

```
>>> init press = 4000
>>> bubble_press = 2800
>>>
>>> init_press == bubble_press # == denotes equal to
False
>>> init_press != bubble_press # != denotes not equal to
True
>>> init_press > bubble_press # > denotes greater than
True
>>> init_press < bubble_press # < denotes greater than
False
>>> init_press >= 4200 # >= denotes greater than or equal to
False
>>> init_press <= 4200 # <= denotes less than or equal to
True
>>> init_press is bubble_press # is denotes the same as
False
>>> init_press is 4000 # is denotes the same as
False
>>> init_press is not bubble_press # is not denotes not the same as
True
```

#### Conditional Statements

## Logical Operators

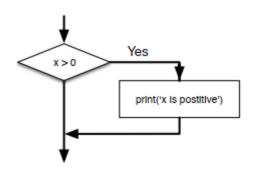

- Sometimes, multiple conditions needed to be checked in a conditional statement.
- Logical operators are used to combine boolean expressions
  - and returns True if all conditions are true, true, otherwise, False is returned.
  - or returns True if one of the conditions is true, otherwise, False is returned.
- >>> 2<3 and 7>5 True >>> 2<3 and 7<5 False >>> 2<3 or 7<5 True >>> not(7<5) True

- Logical operators are also used to negate boolean expressions
  - not returns True for a false condition and vice-versa

#### Conditional Statements

### if... Statement (Conditional Execution)

- if statements evaluates the given condition; performs the given statement(s) if condition is true and skips the given statement(s) if condition is false.
- The condition(s) is written after the *if* keyword and ended with a colon i.e. (:)
- The statements to be performed or skip are written as an indented block in subsequent line(s).
- Remove the indentation in lines after the if block.

```
if perm > 50:
          print('Good permeability')
Good permeability
```

### Conditional Statements

if... Statement (Conditional Execution)

# Petroleum engineering application

- Computing pseudo-critical gas properties using Sutton's correlation
  - $\bullet$  Sutton developed a correlation for estimating for estimating  $P_{pc}$  and  $T_{pc}$  as functions of gas gravity.
  - Here is the first step in Sutton's procedure:
    - If the gas mixture contains <12 mol% of CO<sub>2</sub>, < 3% of Nitrogen and no H<sub>2</sub>S, then the parameter  $\gamma_h$ takes the same value as the given separator gas gravity ( $\gamma_{g}$ ) or the given well-stream gravity ( $\gamma_{w}$ )
    - However, if gas mixture contains >12 mol% of CO<sub>2</sub>, >3% of Nitrogen and any H<sub>2</sub>S, then the parameter  $\gamma_h$  is determined thus:

$$\gamma_h = \frac{\gamma_w - 1.1767 y_{H_2S} - 1.5196 y_{CO_2} - 0.9672 y_{N_2} - 0.622 y_{H_2O}}{1 - y_{H_2S} - y_{CO_2} - y_{N_2} - y_{H_2O}}$$

#### Conditional Statements

if... Statement (Conditional Execution)

# Petroleum engineering application

- Computing pseudo-critical gas properties using Sutton's correlation
  - The first step in Sutton's can be executed with an if ... statement.
  - Observe that the procedure implies that if any of the impurities in the gas exceeds the stated threshold value, then, the given gas gravity  $(\gamma_w)$  need to be corrected for the effects of the impurities, using the given equation.
  - However, the correction task should be neglected if none of the impurities exceeds its threshold value.

#### Conditional Statements

if... Statement (Conditional Execution)

# Petroleum engineering application

- Computing pseudo-critical gas properties using Sutton's correlation
  - To execute this procedure, we simply construct a Boolean condition to test if any threshold is violated.
  - If the condition is evaluated as True, then a block of statement to perform the gs gravity correction is executed.
  - If the condition is evaluated to be False, there is no need for the correction, hence, the block of statement is skipped.

#### Conditional Statements

if... Statement (Conditional Execution)

# Petroleum engineering application

Computing pseudo-critical gas properties using Sutton's correlation

```
co2 comp > 0.12 or n2 comp > 0.03 or h2s comp > 0:
 gas gravity = (gas gravity - (1.1767*h2s comp) - \
            (1.5196*co2 comp) - (0.9672*n2 comp) - \
             (0.622*h2o comp))/(1- h2s comp - co2 comp - n2 comp - h2o comp)
 print('The corrected gas gravity is', gas gravity)
```

The full script for this computation is available here

#### Conditional Statements

if... Statement (Conditional Execution)

# Assignment 2

Upgrade the demo\_gas\_grav\_corr.py script (hosted on TTOWG/ PET328\_2021\_Class GitHub repository) to perform the entire Sutton's procedure. Save the upgraded script as sutton\_correlation.py, commit and push it to your GitHub repository. Submit the URL to your copy of PET328\_2021\_Class repository. Furthermore, send a pull request to the original TTOWG/ PET328\_2021\_Class repository.

The complete Sutton's algorithm is available <u>here</u>.

#### Conditional Statements

if... Statement (Conditional Execution)

# Assignment 2

You may test run your script with the following data:

#### Inputs

- $y_{CO2} = 0.0164$
- $y_{N2} = 0.0236$
- $y_{H2S} = 0.1841$
- **G**as gravity = 0.6992

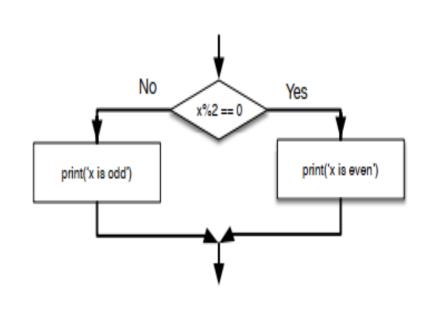

#### Outputs

- Corrected gas gravity = 0.5604
- Ppch = 682.3 psia.
- ♣ Tpch = 341.8 deg Rankine
- Ppc = 799.0 psia.
- ♣ Tpc = 403.3 deg Rankine

#### Conditional Statements

## if...then...else Statement (Alternative Execution)

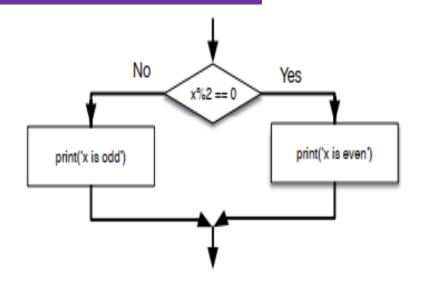

- The if...then...else structure is deployed when there are two alternative tasks and a condition that determines which of the two alternatives should be executed.
- Essentially, there will be a Boolean condition, and two blocks (branches) of statements.
- The first branch (after the condition) is to be executed if the condition evaluates to True while the second branch (after the keyword 'else') is executed if the condition evaluates to False.

#### Conditional Statements

# if...then...else Statement (Alternative Execution)

- The condition(s) is written after the *if* keyword and ended with a colon i.e. (:)
- Then, the statement(s) to be performed if condition is True (i.e., Branch True) are written as an indented block in subsequent line(s).
- Thereafter, the keyword 'else' is written on the next line just after the Branch True. The 'else' keyword should be indented to the same level as the 'if' keyword.
- Finally, the statement(s) to be performed if condition is False (i.e., Branch False) are written as an indented block in subsequent line(s).

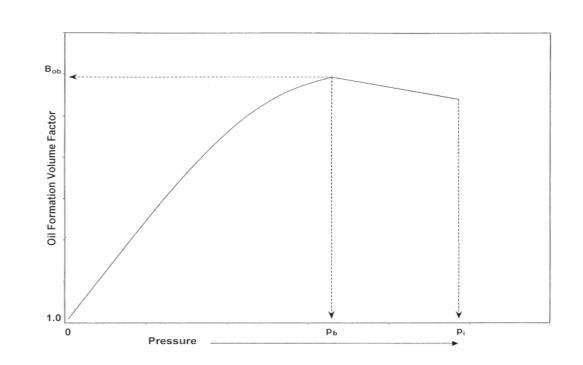

```
>>> if perm < 50:
          print('Fair!')
else:
          print('Good!')
Good!
```

#### Conditional Statements

if...then...else Statement (Alternative Execution)

- Computing oil formation volume factor, Bo.
  - The variation of oil formation volume factor, Bo, with pressure is divided into two pressure regimes, as shown.

#### Conditional Statements

if...then...else Statement (Alternative Execution)

# Petroleum engineering application

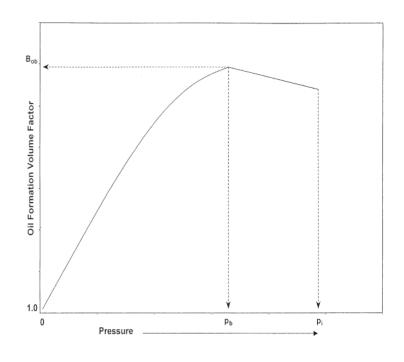

Computing oil formation volume factor, Bo.

For pressures below or equal to bubble point, Standing's correlation for calculating Bo is herein presented:

$$B_0 = 0.9759 + 0.00012F^{1.2} ---- -2.35$$

Where 
$$F = R_s \left(\frac{\gamma_g}{\gamma_o}\right)^{0.5} + 1.25T_F --- -2.36$$

Note: T<sub>F</sub> is temperature in degree Fahrenheit.

#### Conditional Statements

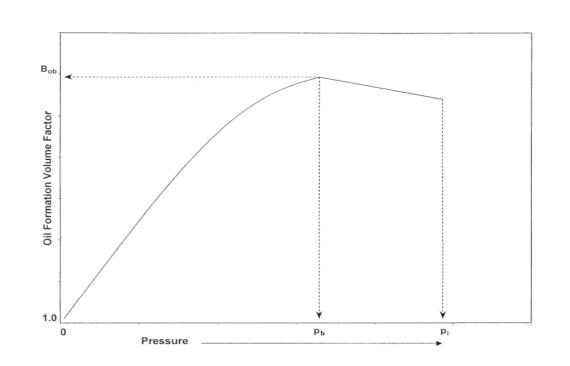

if...then...else Statement (Alternative Execution)

# Petroleum engineering application

Computing oil formation volume factor, Bo. For pressure above bubble point, the analytical equation for computing Bo is given as:

$$B_0 = B_{\rm ob}e^{[c_0(P_b-P)]} --- -2.37$$

Bob is the Bo at bubble point and can be computed using Equations 2.35 and 2.36

#### Conditional Statements

if...then...else Statement (Alternative Execution)

- Computing oil formation volume factor, Bo.
  - To execute this procedure, we simply construct a Boolean condition to test if the current reservoir pressure, p, is greater than the bubble-point pressure of the reservoir.
  - If the condition is evaluated as True, then a block of statement to implement Equation 2.37 is executed.
  - Else, if the condition is evaluated to be False, then a block of statement to implement Equation 2.35 is executed.
  - Note that Equation 2.36 need to be implemented for either of the alternatives, hence, the line to execute it is written before the if...then...else statement.

#### Conditional Statements

if...then...else Statement (Alternative Execution)

# Petroleum engineering application

Computing oil formation volume factor, Bo.

```
# calculating F parameter
F = (rs*((gas\_gravity/oil\_gravity)**0.5))+(1.25*tf)
# the if-then-else statement
f p > pb:
  bob = 0.9759+(0.00012*(F**1.2))
  bo = bob*(math.exp(co*(pb-p)))
   bo = 0.9759+(0.00012*(F**1.2))
```

The full script for this computation is available <u>here</u>.

#### Conditional Statements

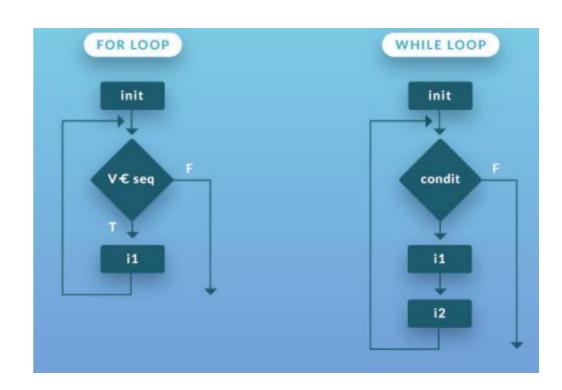

# Reading Assignment

♣ Read on Chained Conditionals (if...elif... statements) and Nested Conditionals, in the recommended textbook for this course (pages 34 – 36)

Recommended Textbook: Python for Everybody: Exploring Data using Python 3, by Charles Severance.

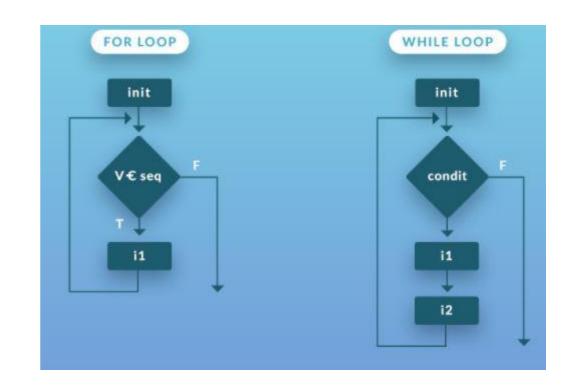

# Repeated Execution

- One major reason for writing computer programs is to automate repetitive workflows.
- When a given task is to be performed repeatedly for each member of a set of entities, that is a repetitive workflow.
- ln implementing such workflows, moving from one entity to the next entity is called looping or iterating.

# Repeated Execution

- Sometimes, the list of entities in the set is known explicitly and presented to the computer that is a definite loop.
- At other times, the list is not known explicitly, rather the computer is asked to perform the task repeatedly until a given condition becomes False that is an indefinite loop.
- Definite loops are implemented with 'for' loops and indefinite loops are implemented with 'while' loops.

# Repeated Execution

for... loops

- In practice, 'for' loops are used in counting the number of items/elements in a list or in summing up (aggregating) the results of a computation for every item/element in a list.
- In such cases, a variable to hold the count or sum is normally, created and set to a dummy initial value before the 'for' loop.
- The first line (header) of a 'for' loop begins with the keyword 'for', followed by an iterator variable, followed by the keyword 'in' and lastly, the list of items on which the task is to be performed.
- Statement(s) to implement the task are written as an indented block on subsequent lines after the header.

```
blocks = [1,2,3,4,5]
>>> for block in blocks:
             print('This is Block', block)
This is Block 1
This is Block 2
This is Block 3
This is Block 4
This is Block 5
```

# Repeated Execution for... loops

#### Iterator variable

- The iterator variable is a sort of temporary variable that represent the item/element of the set being treated in the current loop cycle.
- So, the iterator variable changes value as the program loops through the list of items.
- Sometimes, the in-built function *range* is used to generate the list of items.

```
>>> blocks = [1,2,3,4,5]
>>> for block in blocks:
             print('This is Block', block)
This is Block 1
This is Block 2
This is Block 3
This is Block 4
This is Block 5
>>>
```

```
>>> list(range(5))
[0, 1, 2, 3, 4]
>>> list(range(1,5))
[1, 2, 3, 4]
>>> list(range(1,6))
[1, 2, 3, 4, 5]
```

```
for point in range(1,6):
             print('This is Point', point)
This is Point 1
This is Point 2
This is Point 3
This is Point 4
This is Point 5
```

# Repeated Execution

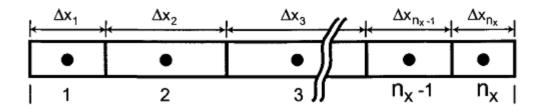

for... loops

- Reservoir discretization
  - Input parameters required to solve reservoir engineering models are essentially rock and fluid properties.
  - These rock and fluid properties are known to vary across the reservoir heterogeneity.
  - The challenge: which value of a property is to be used in solving the model for a given reservoir???
  - Average??? Nay!
  - Locally-acceptable values??? Yes!

# Repeated Execution

for... loops

- Reservoir discretization
- Discretization is the means by which locally-acceptable values of reservoir rock and fluid properties are honored in reservoir modelling.
- Loosely speaking, reservoir discretization is the division of the reservoirs into grid-blocks whose properties, dimensions and locations are well defined and uniform.
- Upon discretizing the reservoir into blocks; the flow model would then need be written and solved, repeatedly, for each block.

# Repeated Execution for... loops

- Reservoir discretization
- Blocks Ordering (Numbering) Schemes
  - a way to identify each block in 1D, 2D or 3D discretized model.
  - Two types of ordering:
    - Engineering ordering.
    - Natural ordering

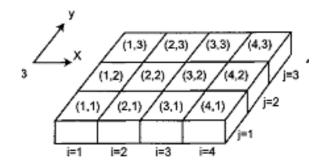

k=3

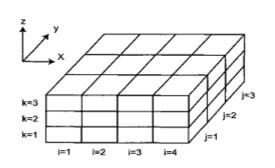

k=1

#### GETTING STARTED WITH PYTHON

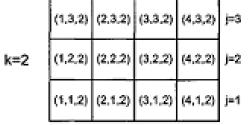

# Repeated Execution for... loops

- Reservoir discretization
- Engineering Ordering
  - uses i, j, k, notations to order blocks in the x, y, z directions respectively.
    - i − counts columns along a certain row;
    - j counts rows along a certain column;
    - k refers to layers.

(1,3,3)	(2,3,3)	(3,3,3)	(4,3,3)	j≃3
(1,2,3)	(2,2,3)	(3,2,3)	(4,2,3)	j=2
(1,1,3)	(2.1,3)	(3,1,3)	(4,1,3)	j=1

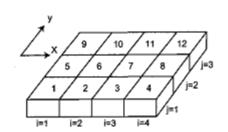

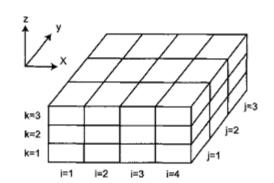

(1,1,1)	(2,1,1)	(3,1,1)	(4,1,1)	j=1
(1,2,1)	(2,2,1)	(3,2,1)	(4,2,1)	j=0
44.00.40	40.0.41			
(1,3,1)	(2,3,1)	(3,3,1)	(4,3,1)	j=(

# Repeated Execution for... loops

# Petroleum engineering application

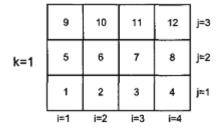

- Reservoir discretization
- Natural Ordering
  - uses natural counting scheme.
  - Columns are counted fastest, followed by rows and then layers.

	33	34	35	36	j≈3
<b>(=3</b>	29	30	31	32	j=2
	25	26	27	28	j=1

	21	22	23	24	j=3
=2	17	18	19	20	j≈2
	13	14	15	16	j≈1

(c) Natural ordering of blocks.

# Repeated Execution

for... loops

- Reservoir discretization
- The engineering ordering fits perfectly well into the 'for' loop scheme.
  - Looping through columns in a given row would be implemented by a column 'for' loop whose iterator variable would be i (the column counter).
  - Looping through rows in a given layer would be implemented by a row 'for' loop whose iterator variable would be j (the row counter).
  - Looping through layers would be implemented by a layer 'for' loop whose iterator variable would be *k* (the layer counter).

# Repeated Execution

for... loops

- Reservoir discretization
- In a one-dimensional discretized model (i.e. a model discretized in only one direction), only one 'for' loop is needed; it may be column, row or layer loop.
- In a multi-dimensional discretized model (i.e. a model discretized in multiple directions), multiple nested 'for' loops are needed; with the column loop cycling faster than the row loop and the row loop cycling faster than the layer loop.
- In nested loop, the innermost loop cycles fastest while the outermost loop cycles the slowest.

### Repeated Execution

for... loops

- Reservoir discretization
- While the engineering ordering is used in computations, communicating outputs of such computations is better done with natural ordering.
- The following equation can be used to obtain the natural ordering index of a block from its engineering ordering indices (i, j, k)

$$n_{order} = [(k-1)n_x \cdot n_y] + [(j-1)n_x] + i$$

- $\bullet$   $n_{order}$  = natural order index of the block
- i is the column index of the block
- j is the row index of the block
- k is the layer index of the block
- $\bullet$  n<sub>x</sub> is the number of blocks in x-direction (i.e. number of columns)
- n<sub>v</sub> is the number of blocks in y-direction
- A constant value of 1 is used for any of the i, j, k indices not relevant to a case at hand.

# Repeated Execution

for... loops

# Petroleum engineering application

- Computing STOIIP for a discretized reservoir model
- The amount of stock tank oil in-place in a given reservoir is given thus:

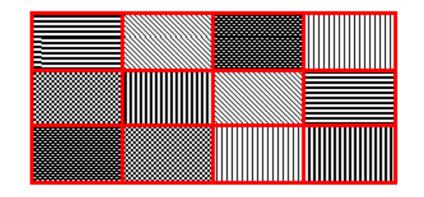

$$STOIIP = \frac{7758Ah\phi(1-S_{wi})}{B_{oi}}$$

 $\bullet$  Typically, values of porosity ( $\phi$ ) and initial water saturation varies across the reservoir; hence, the given reservoir is discretized and the STOIIP equation is implemented for each block of the discretized model. The STOIIP for each is block aggregated in a running total to yield the reservoir STOIIP ultimately.

# Repeated Execution

for... loops

- Computing STOIIP for a discretized reservoir model
- Here is a simple (trivial) 2D example of the grid of such discretized reservoir models.

Legend				
	poro	swi		
	0.1	0.23		
	0.25	0.29		
	0.29	0.31		
	0.33	0.37		
	0.23	0.20		
	0.27	0.28		

# Repeated Execution

for... loops

# Petroleum engineering application

Computing STOIIP for a discretized reservoir model

```
# the 'for' loop
for j in range(1,ny+1):
   for i in range(1,nx+1):
     block n order = (nx^*(j-1))+i
      poro = float(input('What is the value of porosity for Block {0}?'.format(block_n_order)))
     sw = float(input('What is the value of water saturation for Block {0}?'.format(block_n_order)))
     block_stoiip = (7758*area*h*poro*(1-sw))/boi
     total stoiip = total stoiip + block stoiip
      print('The amount of oil in Block {0} is {1:.2f} STB'.format(block_n_order, block_stoilp))
```

The full script for this computation is available <u>here</u>.

Disclaimer: the implementation of this task as presented in the script is only for pedagogical purposes; in reality, a more efficient implementation would be done.

#### Repeated Execution

for...loops

# Assignment 3

An undersaturated oil reservoir material balance simulator computes the cumulative oil produced from a block, in a discretized model, thus:

- $ightharpoonup N_p$  is the cumulative oil produced from a given block.
- N is the initial oil in-place (STOIIP) for each block (assumed constant for all blocks)
- B<sub>oi</sub> is the initial oil formation volume factor (assumed constant for all blocks)
- c<sub>e</sub> is the effective compressibility (assumed constant for all blocks)
- P<sub>i</sub> is the initial reservoir pressure (assumed constant for all blocks)
- P<sub>now</sub> is the current reservoir pressure (varies across blocks depending on proximity to producer well)
- B<sub>o</sub> is the current value of the oil formation volume factor (depends on current pressure in a block)

### Repeated Execution

for... loops

### Assignment 3

 $\triangleright$  Below is the expression to calculate the  $B_o$  value corresponding to a given current pressure. 

- Given a set of parameter ( $N_p$ ,  $B_{oi}$ ,  $B_{ob}$ ,  $c_e$ ,  $c_o$  and  $P_i$ ) values and a grid of current pressure values, write a Python script to implement Equations P5 and P6 for each block. Also include statements to sum up and present the total cumulative oil produced from the entire reservoir.
- Save the script as *mat\_bal.py*, commit and push it to your GitHub repository. Submit the URL to your copy of PET328\_2021\_Class repository. Furthermore, send a pull request to the original TTOWG/ PET328\_2021\_Class repository.

### Repeated Execution

for... loops

# Assignment 3

You may test your script with the following data:

#### Parameters

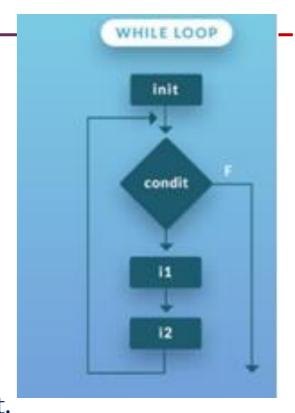

- $\triangleright$  N = 200,779.157 STB
- $P_i = 4025 \text{ psi}$
- $P_{b} = 3330 \text{ psi}$
- $\bullet$  B<sub>oi</sub> = 1.2417 RB/STB
- $\bullet$  B<sub>ob</sub> = 1.2511RB/STB
- $c_e = co = 0.0000113 \text{ psi}^{-1}$

#### Current pressure values in grid:

4018.913	4018.875	4018.802	4018.699
4018.905	4018.866	4018.79	4018.682
4018.89	4018.848	4018.765	4018.648

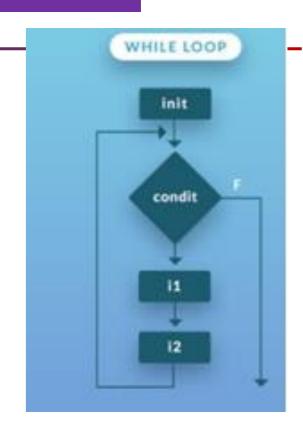

# Repeated Execution while... loops

- Indefinite loops are implemented with 'while' loops.
- Unlike 'for' loops, a definite list of items to be acted upon is not presented to 'while' loops.
- Rather, 'while' loops performs a given block of statement(s) until a specified condition is evaluated to be False; then it stops.
- The loop runs if the specified condition is True, just like an 'if' statement.
- However, unlike an 'if' statement, the 'while' loop repeats the block of statement(s).

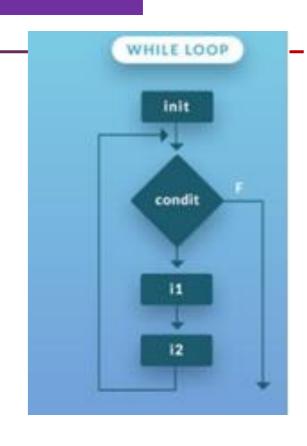

# Repeated Execution while... loops

- The execution of 'while' loops goes thus:
  - Evaluate the specified condition
  - If condition is False, exit the loop and continue with statements(s) outside (below) the loop.
  - Execute the block of statement(s) if condition is true and return to evaluation step

# Repeated Execution while... loops

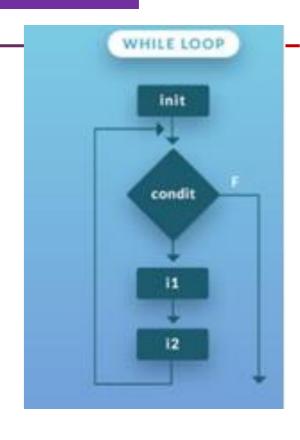

- The 'while' loop condition is constructed as Boolean expression.
- Typically, the condition involves an iterator variable that is normally initialized outside (before) the loop and gets updated in the loop (during each iteration).
- lt is by such changes (updates) to the value of the iterator variable that the condition would eventually turn False and the loop gets terminated.

# Repeated Execution while... loops

When the iteration variable is not specified or not updated, the loop runs forever – infinite loops.

- 4
- Reading Assignment:
  - Read on Infinite Loops, 'break' and 'continue' statements in the textbook recommended for this course.

# Repeated Execution while... Loops

- The 'while' loops finds applications in cases where a task need to be performed for a series of dynamically-changing values of a variable (like pressure) until that variable violates a specified threshold value.
- For instance, in scripting an undersaturated oil reservoir simulator, computations are to be performed for series of decreasing pressure values until pressure reduces to a value below bubble-point pressure.

# Repeated Execution while... Loops

### Petroleum engineering applications

See a trivial example here.

```
>>> current pressure = 4000
>>> bubble_pressure = 2800
>>> while current pressure > bubble pressure:
         print('Pressure {0} is still undersaturated, perform computations'.format(current_pressure))
         current_pressure = current_pressure - 200
Pressure 4000 is still undersaturated, perform computations
Pressure 3800 is still undersaturated, perform computations
Pressure 3600 is still undersaturated, perform computations
Pressure 3400 is still undersaturated, perform computations
Pressure 3200 is still undersaturated, perform computations
Pressure 3000 is still undersaturated, perform computations
```

# Repeated Execution

while... Loops

# Petroleum engineering applications

• Updating oil formation volume factor (Bo), for undersaturated reservoir simulation. Recall that, the analytical equation for computing Bo, at pressures above bubble point is given as: (see Slide 75 - 76)

$$B_{\rm o} = B_{\rm ob}e^{[c_{\rm o}(P_{\rm b}-P)]} --- -2.37$$

There is a need to write statement that would not just compute Bo at a single pressure value, but at series of decreasing pressure values until pressure decreases to bubble point pressure, at which point, the simulation must be terminated.

# Repeated Execution while... Loops

# Petroleum engineering applications

• Updating oil formation volume factor (Bo), for undersaturated reservoir simulation.

```
while p > pb:
  bo = bob*(math.exp(co*(pb-p)))
   print('The value of oil FVF at {0:.2f} psi is {1:.4f}'.format(p, bo))
  p = p - pressure step
# continuing after the 'while' block
print('Bubble-point pressure reached! End of simulation')
```

The full script for this computation is available <u>here</u>.

# Functions (Reusable Code)

- Sometimes, you write a code (sequence of statements) to perform a task, and you realize you often perform that task; may be in the same program, or in other programs.
- Prou don't want to keep writing (or copying) same code anytime you need to perform such task.
- You may give the code (sequence of statements) a cute name; so that anytime that task is to be performed, you simply call that name and the entire sequence of statements in the code get executed!
- Such named sequence of code is known as functions.

# Functions (Reusable Code)

- Benefits of writing functions:
  - Saves typing efforts
  - Reduces the risk of mistakes
  - Help to organize your codes
  - Makes your code more readable
- Take note, functions (named sequence of statements) are objects just as variables (named values) are objects.
- The installed (base)Python itself thrives on a lot of in-built functions such as print, input, range, min, max, len, float, int, str etc.
- Functions created (defined) by users (i.e. not built into Python during installation) are known as user-defined functions.

- Function Definition:
- The first line (header) of a function definition starts with the keyword def, followed by the name of the function (as chosen by you), followed by a comma-separated list of function argument(s) enclosed in parenthesis, and finally, a colon.
- If the function requires no arguments, an empty parenthesis () is typed.

```
#...TTOWG!
# function definition
 ef stoiip_calc(area, thickness, poro, sw, boi):
  STOILP = (7758*area*thickness*poro*(1-sw))/boi
  return STOIIP
```

- Function Definition:
- The sequence of statements (to be executed whenever the function is called) is known as the body of the function, and is written in subsequent indented lines after the function's header.
- A statement specifying the value(s) to be returned by the function must be included with the keyword return

```
#...TTOWG!

# function definition

def stoiip_calc(area, thickness, poro, sw, boi):

STOIIP = (7758*area*thickness*poro*(1-sw))/boi

return STOIIP
```

- Function Arguments:
- The arguments of a function are the values that that it would need to execute its sequence of statements when called.
- When defining a function, placeholders (variables) corresponding to these arguments are named and listed.
- When the function is called, actual values for the arguments are specified (more on this, soon).

```
#...TTOWG!

# function definition

def stoiip_calc(area, thickness, poro, sw, boi):

STOIIP = (7758*area*thickness*poro*(1-sw))/boi

return STOIIP
```

- Function Arguments:
- Default arguments
- ♣ In some cases, some arguments may have default values a standard value to take if value is not provided in the function call.
- Such default value is to be assigned to the concerned argument name at the point of defining the function.
- All such default arguments should only be listed after all un-defaulted arguments have been listed.

# Functions (Reusable Code)

- Function Arguments:
- Default arguments
- Example: the density of a real gas (in  $lb/ft^3$ ) is computed thus:

$$\rho_g = \frac{2.7P\gamma_g}{zT}$$

While the equation above works for gas density at any given values of pressure and temperature; often, engineers want to compute gas density specifically at standard values of pressure (14.7 psia) and temperature (520°R). At these values, z takes a standard value of 1.0.

- Function Arguments:
- Default arguments
- In this example, the function might be defined to accommodate these default values.
- However, the user may still specify other values for these default arguments when calling the function (more on this, soon).

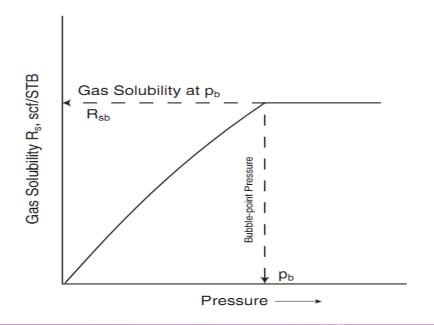

```
#...TTOWG!
# Real gas density function definition
# Note: pressure must be in psia and temperature in degree Rankine
def density(gravity, pressure = 14.7, temperature = 520, z = 1):
  gas_density = (2.70*pressure*gravity)/(z*temperature)
  return gas_density
```

- Return value:
- A function should have a return statement specifying an output to be returned when called.
- The value to be returned is typically an output generated by one of the statements in the function; not necessarily the last output in the sequence.
- A collection of more than one value may be returned.

```
#...TTOWG!
# function definition
   f stoiip_calc(area, thickness, poro, sw, boi):
   STOIIP = (7758*area*thickness*poro*(1-sw))/boi
   return STOIIP
```

```
def stoiip_calc2(area, thickness, poro, sw, boi):
  BV = area*thickness
  PV = BV*poro
  STOIIP = (7758*PV*(1-sw))/boi
  return PV, STOIIP # returning multiple values
```

- Return value:
- Alternative return values may exist, if the task involved a conditional execution.
- When no return value is specified, the function simply return a special value called None.

```
TTOWG!
# A function to compute solution gas-oil ratio, Rs
 def rs_calc(t, p, gravity, api, pb):
   y = (0.00091*t)-(0.0125*api)
   if p<pb:
     rs = gravity*(((p)/(18*(10**y)))**1.204)
     return rs
     rsb = gravity*(((pb)/(18*(10**y)))**1.204)
     return rsb
```

# Functions (Reusable Code)

- Calling a Function
- A function (already defined) is called simply by typing its name and a list of its argument values enclosed in parenthesis.
- If the function requires no arguments, an empty parenthesis () is typed.

# function call for Reservoir TTOWG\_1 (re-use) stoiip\_calc(40, 15, 0.3, 0.28, 1.2)

# function call for Reservoir TTOWG\_2 (re-use) stoiip\_calc(80, 10, 0.23, 0.35, 1.1)

- Calling a Function
- If a function call is assigned to a variable on the LHS of the call statement, upon execution, the return value of the function is stored in that variable.

```
# function call for Reservoir TTOWG_1 (re-use)

oil_inplace_TTOWG_1 = stoiip_calc(40, 15, 0.3, 0.28, 1.2)

print('The amount of oil in place in Reservoir TTOWG_1 is', oil_inplace_TTOWG_1, 'STB')
```

- Calling a Function
- For functions that returns multiple values, the function call may be assigned to multiple variables on the LHS of the call.
- In that case, the return values are unbundled into respective LHS variables.
- Otherwise all the return values are stored into the single LHS variable as a collection.

```
>>> Pore_Vol, N = stoiip_calc2(40,15,0.3,0.28,1.2)
>>> print(Pore Vol)
180.0
>>> print(N)
837864.0
```

```
>>> Volumetrics = stoiip_calc2(40,15,0.3,0.28,1.2)
>>> print(Volumetrics)
(180.0, 837864.0)
```

# Functions (Reusable Code)

- Calling a Function
- Specifying arguments
- In specifying values of arguments, users don't have to necessarily indicate names of the arguments as stated during the function definition.
- Users only have to specify the argument values in the order that they were listed during definition – this is known as positional argument specification.
- Sometimes, the values to be passed to a function call might have been previously assigned to a variable; such variable name may be passed in place of the value.

```
# function call for Reservoir TTOWG_1 (re-use)
stoiip_calc(40, 15, 0.3, 0.28, 1.2)
```

```
drainage_area = 40
payzone_thickness = 15
```

print(stoiip\_calc(drainage\_area, payzone\_thickness, 0.3, 0.28, 1.2))

- Calling a Function
- Specifying arguments
- Alternatively, argument values may be specified alongside the names listed during the function definition.
- ₱ In this case, specifying the arguments don't have to be in a specific order this is known as keyworded argument specification.
- Caution: the names must be typed exactly, as typed during definition.

```
# function call with keyworded argument specification (ordered)
print(stoiip_calc(area = 40, thickness = 15, poro = 0.3, sw = 0.28, boi = 1.2)) # positional argument specification
# function call with keyworded argument specification (unordered)
print(stoiip calc(poro = 0.3, area = 40, boi = 1.2, thickness = 15, sw = 0.28)) # positional argument specification
```

- Calling a Function
- Specifying arguments
- Positional argument specification versus Keyworded argument specification
- Positional argument specification saves typing efforts and reduces the risk of error in naming; requires you know the order of the argument.
- Keyworded argument specification makes no demand on the order, but requires you know the exact name of the arguments.

- Calling a Function with Defaulted Arguments
- When default value argument are present, both specification approach may be mixed in a function call.
- In such case, the un-defaulted (compulsory) arguments must first be specified positionally while the defaulted (optional) arguments may be specified with keywords.
- Take note that the fact that an argument is already defaulted does not imply that a user cannot specify another value.
- In cases where a user need to specify all compulsory arguments and some (not all) optional arguments; it is advisable that keywords be used.
- In general, positional arguments specification can only be used for arguments preceding the first skipped optional arguments.

# Functions (Reusable Code)

- Calling a Function with Defaulted Arguments
- Given that function gas\_density has been defined thus:

def gas\_density(gravity, pressure = 14.7, temperature = 520, z = 1):
 density = (2.70\*pressure\*gravity)/(z\*temperature)
 return round(density, 4)

- Calling a Function with Defaulted Arguments
- The following calls (except one) are equivalent:

```
>>> print(gas_density(0.786, 14.7, 520, 1)) # all positionally specified
0.06
>>> print(gas_density(gravity = 0.786, pressure = 14.7, temperature = 520, z = 1)) # all keyworded
0.06
>>> print(gas_density(0.786)) # all optional omitted
0.06
>>> # Below, temperature specified with keyword because pressure has been skipped
>>> print(gas_density(0.786, temperature = 520))
0.06
>>> # Below, pressure specified positionally because no argument has been skipped yet.
>>> print(gas_density(0.786, 14.7))
0.06
>>> # Below, temperature wrongly specified positionally, got interpreted as pressure
>>> print(gas_density(0.786, 520))
2.1222
```

# Functions (Reusable Code)

- Calling a Function
- Function Availability
- Before a function is called in a script (program), it must be made available in that script.
- A function could be made directly available in a script by defining it in the same script where it

is called.

```
#defining function stoilp
   f stoiip(area, thickness, poro, sw, boi):
   N = (7758*area*thickness*poro*(1-sw))/boi
   return round(N, 2)
# the 'for' loop
for j in range(1,ny+1):
   for i in range(1,nx+1):
     block n order = (nx^*(j-1))+i
      poro = float(input('What is the value of porosity for Block {0}?'.format(block n order)))
     sw = float(input('What is the value of water saturation for Block {0}?'.format(block n order)))
     block stoiip = stoiip(area, h, poro, sw, boi)
     total_stoiip = total_stoiip + block_stoiip
      print('The amount of oil in Block {0} is {1:.2f} STB'.format(block_n_order, block_stoiip))
```

- Calling a Function
- Function Availability
- Sometimes, a function defined in script (defining script) needed to be called in another script (calling script). To avoid clumsiness, you may not want to copy the function definition to the calling script; in such cases, you simply *import* the function.

- Calling a Function
- Function Availability
- Importing Functions
- You may import function(s) using the following approaches:
- Given that function *stoiip* has been defined in script (file) *peteng.py* 
  - View the content of peteng.py here.

- Calling a Function
- Function Availability
- Importing Functions
- Approach 1: Import the entire file

```
# importing the file where stoil is defined
import peteng
# the 'for' loop
for j in range(1,ny+1):
   for i in range(1,nx+1):
     block n order = (nx*(j-1))+i
     poro = float(input('What is the value of porosity for Block {0}?'.format(block_n_order)))
     sw = float(input('What is the value of water saturation for Block {0}?'.format(block_n_order)))
     block_stoiip = peteng.stoiip(area, h, poro, sw, boi)
     total_stoiip = total_stoiip + block_stoiip
     print('The amount of oil in Block {0} is {1:.2f} STB'.format(block_n_order, block_stoiip))
```

- Calling a Function
- Function Availability
- Importing Functions
- Approach 1: Import the entire file
  - Notes:
    - In this case, the whole content of the file (function stoiip and others) is imported.
    - Calling any function in the imported file must be preceded with the file name and a period(.); e.g. peteng.stoiip(...)

- Calling a Function
- Function Availability
- Importing Functions
- Approach 2: From the file, import all functions

```
# importing the file where stoil is defined
 rom peteng import *
# the 'for' loop
for j in range(1,ny+1):
   for i in range(1,nx+1):
     block n order = (nx*(j-1))+i
      poro = float(input('What is the value of porosity for Block {0}?'.format(block_n_order)))
     sw = float(input('What is the value of water saturation for Block {0}?'.format(block_n_order)))
     block_stoiip = stoiip(area, h, poro, sw, boi)
     total_stoiip = total_stoiip + block_stoiip
      print('The amount of oil in Block {0} is {1:.2f} STB'.format(block_n_order, block_stoiip))
```

- Calling a Function
- Function Availability
- Importing Functions
- Approach 2: From the file, import all functions
  - Notes:
    - In this case also, the whole content of the file (function stoiip and others) is imported.
    - The functions should be called without any prefix e.g. stoiip(...)

- Calling a Function
- Function Availability
- Importing Functions
- Approach 3: From the file, import only needed function(s)

```
# importing the file where stoil is defined
from peteng import stoiip
# the 'for' loop
for j in range(1,ny+1):
   for i in range(1,nx+1):
      block n order = (nx*(j-1))+i
      poro = float(input('What is the value of porosity for Block {0}?'.format(block_n_order)))
      sw = float(input('What is the value of water saturation for Block {0}?'.format(block_n_order)))
      block_stoiip = stoiip(area, h, poro, sw, boi)
      total_stoiip = total_stoiip + block_stoiip
      print('The amount of oil in Block {0} is {1:.2f} STB'.format(block_n_order, block_stoiip))
```

- Calling a Function
- Function Availability
- Importing Functions
- Approach 3: From the file, import all functions
  - Notes:
    - In this case, only the function(s) indicated after the keyword import is imported.
    - Here too, the function(s) should be called without any prefix e.g. stoiip(...)

### Functions (Reusable Code)

### Calling a Function

```
>>> # Sample calls to functions defined in peteng.py
>>> from peteng import *
                                                              Fn Ctr # Alt
>>> gas_density(0.786, 14.7, 520, 1)
0.06
>>> bubble pressure(220, 4000, 0.786, 0.8217, 743)
2608.51
>>> sol_gor(220, 4000, 0.786, 0.8217, 2608.51)
743.76
>>> fvf(4000, 220, 0.786, 0.8217, pb = 2608.51, co = 0.00001413) # rs skipped
1.4267
>>> fvf(4000, 220, 0.786, 0.8217, rs = 743.76, co = 0.00001413) # pb skipped
1.4267
>>> fvf(2100, 220, 0.786, 0.8217, rs = 570, pb = 2608.51) # co not required
1.3593
>>> fvf(2100, 220, 0.786, 0.8217, pb = 2608.51) # rs skipped, co not required
1.3608
```

The file peteng.py is available here

The algorithms for various functions in peteng.py are available here

```
>>>#TTOWG!
>>>print('...to the only wise God')
```
